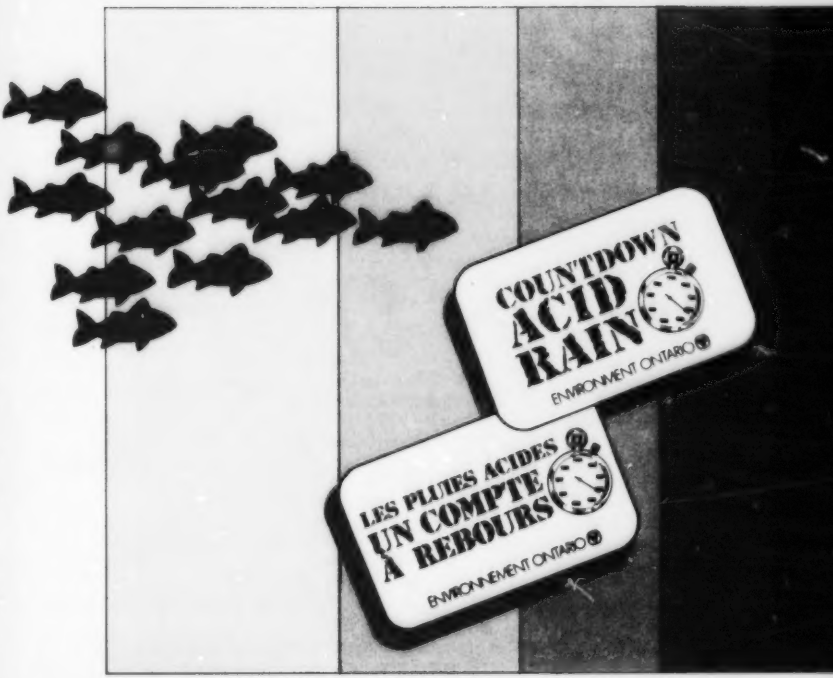
Acid Sensitivity of Lakes in Ontario

Sensibilité des lacs de l'Ontario aux dépôts acides



1988

]DE DE LA SENSIBILITÉ DES LACS DE 'TARIO AUX DÉPÔTS ACIDES – 1988

89-0226I/

Histori

Les précip. ides sont au nombre des problèmes environnementaux les plus mportants de . égions de l'Amérique du Nord. Tout le Sud de l'Ontario est continuellement expo. à des acides, des gaz qui se transforment en acides et d'autres polluants connexes. On doit les dépôts acides à la pluie, à la neige, au brouillard et aux particules en suspension dans l'air lorsqu'ils tombent au sol.

On doit la plus grande partie de ces acides aux activités humaines. Tant au Canada qu'aux États-Unis, les fonderies et les centrales alimentées au charbon rejettent chaque année dans l'atmosphère des millions de tonnes d'anhydride sulfureux. Les voitures, les camions et les trains produisent des millions de tonnes supplémentaires d'oxydes d'azote. Ces gaz réagissent avec la lumière solaire, l'oxygène, l'ozone, l'eau et d'autres gaz pour former de l'acide nitrique et de l'acide sulfurique, qui sont des acides forts et corrosifs.

Dans les régions non polluées, la pluie et la neige sont légèrement acides à l'état naturel, car le gaz carbonique est un composant naturel de l'atmosphère, qui se dissout dans l'eau pour former un acide carbonique faible. L'eau des lacs à l'état naturel atteste du processus chimique qu'engendre la présence de cet acide faible. Les roches et les minéraux réagissent avec l'acide carbonique pour former du bicarbonate que l'on trouve partout dans l'eau à l'état naturel.

Les espèces biologiques complexes qui peuplent les lacs, cours d'eau et forêts ont évolué et se sont adaptées en fonction de ces conditions et processus naturels. Les pluies acides ont cependant sérieusement perturbé cet équilibre.

Degrés d'acidité

On mesure l'acidité d'une solution au moyen d'une échelle de pH. Il s'agit d'une échelle logarithmique, ce qui signifie que tout changement d'une unité dans l'échelle de pH correspond à un degré d'acidité dix fois plus élevé ou plus faible. Par conséquent, une solution dont le pH est de 4,0 est dix fois plus acide qu'une solution dont le pH est de 5,0 et cent fois plus acide qu'une solution dont le pH est de 6,0.

L'eau distillée, qui a un pH de 7,0, n'est ni acide ni alcaline. En raison de la présence de gaz carbonique dans l'atmosphère, le pH de la pluie est de 5,6 environ en l'absence de tout autre facteur.

Les précipitations dont le pH est inférieur à 5,6 sont appelées "précipitations acides"; toutefois, des quantités importantes d'acide proviennent également de dépôts secs de gaz et de particules. Dans presque tout le Sud de l'Ontario, le pH moyen de la pluie est d'environ 4,2. Dans la région éloignée du Nord-Ouest, le pH est en moyenne au-dessus de 5,0. La formation de dépôts acides étant plus importante dans le Sud de l'Ontario que dans le Nord, c'est dans cette partie de la province que l'on trouve le plus grand nombre de lacs acidifiés.

Étude des lacs

La plupart des lacs ont la capacité de neutraliser une certaine quantité d'acide. Cette capacité se mesure au degré d'alcalinité découlant de la présence de bicarbonate dans l'eau. Si un lac a un degré élevé d'alcalinité, il peut résister aux arrivées d'acides, et donc ne pas changer de pH. On peut observer des baisses de pH dans les lacs à faible degré d'alcalinité à l'époque de la fonte des neiges ou lors de pluies abondantes, qui provoquent des arrivées d'acides considérables dans les lacs.

Un lac dont le degré d'alcalinité est de zéro ou moins est un lac acidifié. Les lacs qui ne sont pas alcalins présentent une acidité minérale. Il s'agit de lacs qui ont habituellement un pH de moins de 5,0 et, si l'on y trouve des poissons, ces derniers appartiennent à des espèces robustes et résistantes aux acides, comme la perche. À mesure qu'un lac s'acidifie, les espèces sensibles, dont l'achigan et l'omble, ne peuvent plus se reproduire; il se peut cependant que certains poissons adultes arrivent à survivre et meurent de vieillesse ou d'autres causes.

La capacité d'un lac à neutraliser les acides est fonction d'un certain nombre de facteurs. Les lacs qui sont situés dans des régions calcaires ont en général un degré élevé d'alcalinité, l'alcalinité provenant de la transformation lente du calcaire en bicarbonate. L'alcalinité peut aussi provenir d'eaux souterraines ou de ruissellements qui se déversent dans certains lacs et représentent une part importante de leur capacité à neutraliser les acides.

ACID SENSITIVITY SURVEY OF LAKES IN ONTARIO – 1988

Background

One of the most pressing environmental problems facing large areas of North America is acidic precipitation. All of southern Ontario receives a steady bombardment of acids, acid forming gases and associated pollutants. The acids come down with rain, snow, fog, and small particles in the air.

Human activities are responsible for the large majority of these acids. Smelters and coal-fired electric generating stations both in Canada and the United States spew millions of tonnes of sulphur dioxide into the atmosphere annually. Cars, trucks, and trains contribute more millions of tonnes of nitrogen oxides. These gases react with sunlight, oxygen, ozone, water and other gases to form sulphuric and nitric acid – strong, corrosive acids.

In unpolluted areas, rain and snow are naturally slightly acidic since carbon dioxide, a natural component of the atmosphere, dissolves in water to form weak carbonic acid. Water quality of lakes has developed in response to weathering processes induced by this weak acid. Rocks and minerals react with carbonic acid to form bicarbonate, which is found in natural waters everywhere.

The complex biological communities in lakes, streams and forests have adapted and evolved in equilibrium with these natural conditions and processes. However , acid rain has seriously disturbed this equilibrium.

Levels of Acidity

The acidity of a solution is measured on a pH scale. The pH scale is termed logarithmic. This means that a change of one unit on the pH scale corresponds to a ten-fold increase or decrease in acidity. Thus, a solution with a pH of 4.0 is 10 times more acidic than a solution with a pH of 5.0, and100 times more acidic than a solution with a pH of 6.0.

Distilled water is considered to be neither acidic or alkaline and has a pH of 7.0. The carbon dioxide in the atmosphere will cause rain to have a pH of about 5.6 if no other factors are affecting the pH.

Rainfall with a pH of less than 5.6 is termed "acid rain", but significant amounts of acid are also deposited as gases and particles through a process called "dry deposition." Over most of southern Ontario, the average pH of the rain is about 4.2. In the remote northwest, the average pH is above 5.0. Because acid deposition is higher in southern Ontario than in the northern parts, more acid lakes are found in the south.

Survey of Lakes

Most lakes have the ability to neutralize a certain amount of acid. This neutralizing capacity of a lake is measured by the level of bicarbonate alkalinity in the water. If a lake has a high alkalinity level, it can resist pH changes caused by acid inputs. Lakes with low alkalinities can experience pH depressions during spring snowmelt or after heavy rains, when large acid loads enter the lakes.

A lake with zero or less alkalinity is an acid lake. A negative reading of alkalinity means that the lake contains mineral acidity. These lakes usually have a pH of less than 5.0, and if they have any fish at all, it will be a hardy, acid-tolerant species like yellow perch. As a lake acidifies, sensitive species such as bass and trout will probably not reproduce, although some adult fish may still survive until they die of old age or other causes.

The neutralizing capacity of a lake is dependent on a number of factors. Lakes in limestone regions usually have a very high alkalinity, since bicarbonate alkalinity results as limestone slowly dissolves. Alkalinity can also be generated in soils, so that groundwater and soil runoff to some lakes can significantly increase their neutralizing capacity.

Dans certains cas, le degré d'alcalinité peut également être réduit par des acides qui se forment naturellement au cours du processus de décomposition des feuilles et d'autres matières organiques. On remarque généralement la présence de ces acides à la coloration brune de l'eau, qui est particulièrement visible dans les régions où se trouvent de grandes étendues marécageuses.

Parmi les lacs qui ont une capacité élevée à neutraliser les acides, mentionnons les Grands Lacs, les Kawartha et les lacs du bassin de la rivière Rideau. Par contre, les lacs du Bouclier canadien n'ont généralement qu'une faible capacité à neutraliser les acides. Cette région a un sous-sol granitique et présente de nombreux affleurements rocheux. Le granit est insoluble et ne contribue pour ainsi dire pas à l'alcalinité des lacs. Les sols sont en général peu profonds et ils sont sablonneux ou acides. Leur acidité ne provient pas de dépôts acides mais de la décomposition de matières organiques comme c'est le cas, par exemple, des litières des forêts. Les ruissellements provenant de ces sols ne contribuent donc pas à accroître la capacité des lacs à neutraliser les acides, et c'est pourquoi la plupart des lacs du Bouclier canadien n'ont qu'un faible degré d'alcalinité.

Environnement Ontario, en collaboration avec le ministère des Richesses naturelles, effectue des études pour déterminer le degré de sensibilité des lacs de l'Ontario aux précipitations acides. Ce cinquième rapport résume le résultat des analyses menées dans 6467 lacs de la province et il est publié par le ministère de l'Environnement dans le cadre de son Étude sur les précipitations acides en Ontario. Cette liste étant cumulative, les changements observés dans le nombre de lacs acidifiés comparativement aux publications précédentes reflètent l'ajout de nouveaux lacs et non l'acidification de lacs depuis la publication de la dernière liste.

Le présent bulletin contient une liste alphabétique des lacs analysés jusqu'à présent, répartis par comté ou district; le nom de chaque lac est suivi de l'indication de son degré de sensibilité au processus d'acidification. Il contient également un tableau qui précise le nombre et le pourcentage de lacs dans chaque catégorie d'alcalinité par comté et district.

Le tableau permet de constater, par exemple, que 1617 lacs, soit 25 pour cent des lacs étudiés, ne manifestaient aucune sensibilité à l'acidification et que 17,2 pour cent des lacs, soit 1111, n'y étaient que peu sensibles. Par ailleurs, 2388 des lacs étudiés, soit 36,9 pour cent, étaient modérément sensibles et 1015 lacs, soit 15,7 pour cent, étaient très sensibles. 5,2 pour cent des lacs étudiés, soit 336, étaient acidifiés.

Les lacs de niveau 1 ne sont pas alcalins; ils sont déjà *acidifiés*. De nombreuses espèces – et parfois toutes les espèces – de poissons en sont disparues. Les coques, les escargots et de nombreux amphibiens peuvent en être également absents. Sauf s'ils contiennent des matières organiques naturelles, les lacs de niveau 1 sont d'une limpidité remarquable. On trouve parfois des accumulations d'algues près des rives.

Les lacs de niveau 2 ont un degré d'alcalinité très bas et sont *très sensibles* aux arrivées importantes d'acides. Les ruissellements du printemps peuvent entraîner des baisses de pH et ces lacs ont fréquemment des algues.

Les lacs de niveau 3 sont *modérément sensibles* aux arrivées importantes d'acides. Les poissons et autres êtres vivants courent généralement moins de risques que ceux des lacs de niveau 2.

Les lacs de niveau 4 sont *peu sensibles* et le milieu biologique n'a en général pas été endommagé par les dépôts acides.

Les lacs de niveau 5 sont *insensibles* aux dépôts acides et peuvent absorber d'importantes quantités d'acides lors des ruissellements du printemps sans subir de dommages biologiques. La capacité tampon de ces lacs leur permet de neutraliser les pluies acides indéfiniment.

Les travaux d'échantillonnage et d'analyse se poursuivent et le ministère en publiera périodiquement les résultats.

In some cases, alkalinity levels can also be reduced by naturally occurring acids. These acids are formed during the decomposition of leaves and other organic material. The presence of these acids is usually observed as a brown colouration in water and can be quite noticeable in areas with extensive swamps or bogs.

Examples of lakes with a large acid neutralizing capacity are the Great Lakes, the Kawarthas, and lakes around the Rideau system. Lakes on the Canadian Shield typically have a low acid neutralizing capacity. This region has a granite base and many exposed rock outcrops. Granite is insoluble and can supply little alkalinity. The soils are usually shallow and sandy or acidic. These acidic soils are not the result of acid deposition, but are formed by the decomposition of organic material such as forest litter. Runoff from these soils cannot contribute to the neutralizing capacity of lakes, so that most lakes on the Shield have low alkalinity levels.

Environment Ontario, in cooperation with the Ministry of Natural Resources, conducts lake surveys to determine the sensitivity of Ontario lakes to acidic precipitation. This summary of the survey results includes information on 6467 lakes throughout the province and is issued by Environment Ontario as part of its Acidic Precipitation in Ontario Study (APIOS). This list is cumulative, so changes in the number of acidic lakes from previous brochures reflect new lakes that have been identified, rather than lakes having turned acidic since the last list was published.

The brochure presents an alphabetical list by county or district of the lakes sampled to date, with an indication of the relative sensitivity of each of the lakes to the acidification process. The table provides a summary of the number and percentage of lakes in each alkalinity class organized by county or district.

For example, 25 percent, or 1617 lakes, were found to be not sensitive to acidification, and a further 17.2 percent, or 1111 lakes, had low sensitivity. 36.9 percent, or 2388 lakes, had moderate sensitivity, and 15.7 percent, or 1015 lakes, were extremely sensitive. 5.2 percent, or 336 lakes, were classified as acidic.

Level 1 lakes have zero or negative alkalinity; they have already become *acidic*. Many or all fish species may be absent from such lakes. Clam, snail and many amphibian species may also be absent. Level 1 lakes, unless naturally high in organic colour, are exceptionally clear. Clouds of algae may accumulate in inshore areas.

Level 2 lakes have very low alkalinity and are *extremely sensitive* to heavy acid loadings. Depressions in pH may occur during spring runoff, and algae clouds are also common in these lakes.

Level 3 lakes are *moderately sensitive* to heavy acid loadings. Fish and other biota are generally less at risk in comparison to level 2 lakes.

Level 4 lakes are of *low sensitivity* and are less likely to experience biological damage due to acid deposition.

Level 5 lakes are *not sensitive* to acid loadings and are capable of withstanding heavy acid loadings during spring runoff without biological damage. Such lakes contain sufficient buffering capacity to neutralize acid rain for an indefinite period of time.

Lake sampling and analysis is continuing, and updated lists will be published periodically.

LACS ÉTUDIÉS POUR LEUR SENSIBILITÉ AUX DÉPÔTS ACIDES

Les lacs sont énumérés par comté ou district. Dans certains cas, on a également mentionné les autres noms sous lesquels ces lacs sont couramment désignés. Le nom du canton est inscrit entre parenthèses pour distinguer les lacs portant le même nom dans un même comté ou district.

Le chiffre qui suit le nom du lac indique le degré de sensibilité à l'acidification: (1) acidifié, (2) très sensible, (3) modérément sensible, (4) peu sensible, (5) insensible.

LAKES SURVEYED FOR ACID SENSITIVITY

Lakes are listed according to the county / district. In some cases, commonly used alternatc lake names are also given. Township (Tp) locations are indicated for lakes with the same name from the same county or district.

The number following the lake name indicates the degree of sensitivity to acidification as follows: (1) acidic, (2) extreme sensitivity, (3) moderate sensitivity, (4) low sensitivity, (5) no sensitivity.
